Learning Objectives in this Part of the Lesson

• Understand the structure & functionality of the Java Phaser barrier synchronizer

Class Phaser

java.lang.Object
   java.util.concurrent.Phase

public class Phaser
   extends Object

A reusable synchronization barrier, similar in functionality to CyclicBarrier and CountDownLatch but supporting more flexible usage.

Registration. Unlike the case for other barriers, the number of parties registered to synchronize on a phaser may vary over time. Tasks may be registered at any time (using methods register(), bulkRegister(int), or forms of constructors establishing initial numbers of parties), and optionally deregistered upon any arrival (using arriveAndDeregister()). As is the case with most basic synchronization constructs, registration and deregistration affect only internal counts; they do not establish any further internal bookkeeping, so tasks cannot query whether they are registered. (However, you can introduce such bookkeeping by subclassing this class.)

One human known use is different work-crews with different #'s of workers coordinating to build a house.
Overview of Java Phaser

- Implements yet another Java barrier synchronizer
  - Allows a variable (or fixed) # of threads to wait for all operations performed in other threads to complete before proceeding
  - Well-suited for variable-size "cyclic", "entry", and/or "exit" barriers

A Phaser may be overkill for fixed-sized barriers.

Overview of Java Phaser

- Does not apply the *Bridge* pattern

```java
public class Phaser {
  ...
}
```

See `share/classes/java/util/concurrent/Phaser.java`
Overview of Java Phaser

- Does not apply the *Bridge* pattern
- Nor does it use the Abstract QueuedSynchronizer framework

```java
public class Phaser {
    // ...
}
```
Overview of Java Phaser

- Instead, it defines a # of fields that implement a phaser

  ```java
  public class Phaser {
      private volatile long state;
      ...
  }
  ```

To efficiently maintain atomicity, these values are packed into a single (atomic) long that is updated via CAS operations.
End of Java Phaser: Structure & Functionality
1. What of the following are benefit of the Java Phaser over the CyclicBarrier?

a. It supports fixed-size “cyclic” & “entry” and/or “exit” barriers who # of parties match the # of threads

b. It supports variable-size “cyclic” & “entry” and/or “exit” barriers whose # of parties can vary dynamically

c. It uses the AbstractQueuedSynchronizer framework to enhance reuse

d. They provide better support for fixed-sized # of parties
